1. Setup

- Sampling: GHS picked a set of 2001 census EAs, then sampled HHs and followed these HHs for 3 (or 4) years, then repeated the process with new EAs. Here are counts for EAs in each round within 4km of projects

  1. 2005-2007: 214 EAs
  2. 2008-2012: 236 EAs
  3. 2012-2014: 333 EAs
  4. 2015-2017: 538 EAs

- Empirical strategy:

  - $y_{ite} = \beta_0 + \beta_1 post_t + \beta_2 proj_e + \beta_3 post_t X proj_e + \beta_4 spill_e + \beta_5 post_t X spill_e + \epsilon$
  - e is EA, t is year, i is HH, $post$ is year$\geq$ 2008

- Notes:

  - We're essentially picking up the second half of the constructed project effects. Table 1 finds that in project areas, there's about 20% more subsidized housing in 2005-2007, which jumps by 24% in 2008-2017
  - I don't do the triple-difference because many of the planned but unconstructed projects may be getting finished over this period (I tried it and got weird results consistent with this theory)
  - the **Non-RDP** results limit the sample to **Non-RDP** houses only so we can see what happens to non-project housing quality !
  - errors are clustered at project level, also results are weighted by EA area and control for EA area cubic in pre and post periods

2. Results
